## **Problem** 1

Consider a model where the prior distribution over the parameters is a normal distribution with mean zero and variance  $\sigma_{\phi}^2$  so that

$$Pr(\phi) = \prod_{j=1}^{J} \text{Norm}_{\phi_j}[0, \sigma_{\phi}^2].$$

where j indexes the model parameters. We now maximise  $\prod_{i=1}^{I} Pr(y_i|x_i,\phi)Pr(\phi)$ . Show that the associated loss of this model is equivalent to L2 regularization.

## $\mathbf{2}$ Answer

Bayes Theorem says

$$Pr(H|E) = \frac{Pr(H) \cdot Pr(E|H)}{Pr(E)}$$

In our case

$$Pr(\phi|y) = \frac{Pr(\phi) \cdot Pr(y|\phi)}{Pr(y)}$$

The maximum a posteriori criterion is argmax  $\prod_{i=1}^{I} Pr(y_i|x_i,\phi) Pr(\phi)$  We use a negative log likelihood function by minimising the negative log.

$$\underset{\phi}{argmin} - 1 \cdot \left( log \left( \sum_{i=1}^{I} Pr(y_{i|x_{i},\phi}) \right) + log \left( \sum_{i=1}^{I} Pr(\phi) \right) \right)$$

Expanding out the  $Pr(\phi)$ 

$$\operatorname{Norm}_{\phi_j}[0,\sigma_{\phi}^2] = \frac{1}{\sqrt{2\pi\sigma^2}} \exp(-\phi_j^2/2\sigma^2)$$

So that

$$\log\left(\sum_{i=1}^{I} Pr(\phi)\right) = \sum_{j=1}^{J} -\phi_{j}^{2}/2\sigma^{2} + constant$$

Re-arranging into the canonical form, this is

$$\hat{\phi} = \underset{\phi}{argmin} \left[ \sum_{i=1}^{I} l_i[x_i, y_i] + \lambda \sum_{j=1}^{J} \phi_j^2 \right]$$

This represents L2 regularization.
